

Introduction

This document contains multiple sections of text designed to test the document extraction mode. Each section has a heading followed by body text that should be properly extracted and formatted.

Technical Overview

The system architecture consists of three main components: the frontend user interface built with React, the data processing layer using WebAssembly, and the local storage system using IndexedDB. All processing occurs client-side with zero server communication.

Implementation Details

The text extraction pipeline first attempts to read embedded text from the PDF using pdf.js. If the document contains fewer than 50 characters of embedded text, the system falls back to OCR using Tesseract.js with a rendering scale of 2.0x for optimal accuracy.

Performance Metrics

Average extraction time for a single page is 1.2 seconds for embedded text and 8.5 seconds for OCR. Table detection adds approximately 200ms per page. Export to PDF takes 500ms for documents under 10 pages.

Conclusion

The text extraction tool provides reliable, offline document processing suitable for sensitive environments. Future improvements will include multi-language OCR support and advanced table structure recognition.
